# Fourier transform on compact Hausdorff groups 

Mykola Yaremenko ${ }^{\text {a }}$<br>${ }^{a}$ Department of Partial Differential Equations, The National Technical University of Ukraine, "Igor Sikorsky Kyiv Polytechnic Institute", Kyiv, Ukraine

#### Abstract

This article deals with the generalization of the abstract Fourier analysis on the compact Hausdorff group. In this paper, the generalized Fourier transform $F$ is defined as $F(\psi)(\alpha)=\int \psi(h) M_{\alpha}\left(h^{-1}\right) d \mu(h)$ for all $\psi \in L^{2}(G) \cap L^{1}(G)$, where $M_{\alpha}$ is a continuous unitary representation $M_{\alpha}: G \rightarrow U C\left(C^{n(\alpha)}\right)$ of the group $G$ in $C^{n(\alpha)}$, and its properties are studied. Also, we define the symplectic Fourier transform and the generalized Wigner function $W_{A}(\psi, \varphi)$ and establish the Moyal equality for the Wigner function.

We show that the homomorphism $\pi: G \rightarrow U\left(L^{2}\left(G / K, H_{1}\right)\right)$ induced by $\Lambda: G \times(G / K) \rightarrow U\left(H_{1}\right)$ by $(\pi(\psi))(g, h)=\left(\Lambda\left(h^{-1}, g\right)\right)^{-1}\left(\psi\left(h^{-1} g\right)\right), g \in G / K, h \in G, \psi \in L^{2}\left(G / K, H_{1}\right)$ is a unitary representation of the group $G$, assuming the mapping $h \mapsto(\pi(\psi))(g, h)$ is continuous as morphism $G \rightarrow U\left(L^{2}\left(G / K, H_{1}\right)\right)$.

We study the unitary representation $\tilde{\pi}: G \rightarrow H$ induced by the unitary representation $V: K \rightarrow U\left(H_{1}\right)$ given by $\tilde{\pi}_{g}(\psi)(t)=\psi\left(g^{-1} t\right)$ for all $t \in G / K$.

## 1. Introduction

Let $G$ be a compact communicative group equipped with a Haar measure $\mu$ and let $\hat{G}$ be a Pontrjagin dual group consisting of the characters of $G$. A character of the group $G$ is a continuous homomorphism from $G$ to the first unitary group $U(1)$.

The Fourier transform $F$ of the function $\psi \in L^{2}(G) \cap L^{1}(G)$ is defined by

$$
\begin{equation*}
F(\psi)(\chi)=\int \psi(g) \overline{\chi(g)} d \mu(g) \tag{1}
\end{equation*}
$$

for all $\chi \in \hat{G}$.
The inverse Fourier transform $F^{-1}$ can be expressed by a similar formula

$$
\begin{equation*}
F^{-1}(\psi)(\chi)=\int \psi(g) \chi(g) d \mu(g) \tag{2}
\end{equation*}
$$

for all $\chi \in \hat{G}$.

[^0]Mappings $F$ and $F^{-1}$ are connected so that $F(\psi)\left(\chi^{-1}\right)=F^{-1}(\psi)(\chi)$ and

$$
\begin{align*}
& F(\psi)\left(\chi^{-1}\right)=\int \psi\left(g^{-1}\right) \overline{\chi(g)} d \mu(g)=  \tag{3}\\
& =\overline{\int \overline{\psi\left(g^{-1}\right) \chi(g)} d \mu(g) .}
\end{align*}
$$

Example. Let us consider a special case when the main group $G=R^{n}$ is an additive group. The representation of $R^{n}$ in a Hilbert space $H=L^{2}\left(R^{n}\right)$ of functions $\psi$ on $R^{n}$ is a shift $\tau$ given by $\tau(y, \psi)=\psi(\cdot-y)$. All mappings $\tau(y): R^{n} \rightarrow L^{2}\left(R^{n}\right)$ constitute a semigroup. Assume $\tau(y)$ is bounded on $H=L^{2}\left(R^{n}\right)$ then representation $\tau$ is called the regular representation on $H=L^{2}\left(R^{n}\right)$.

The Fourier transform $F(\psi)$ of $\psi \in L^{2}\left(R^{n}\right) \bigcap L^{1}\left(R^{n}\right)$ is defined by

$$
\begin{equation*}
F(\psi)(\lambda)=\hat{\psi}(\lambda)=\int_{R^{n}} \exp (-i \lambda \cdot x) \psi(g) d x \tag{4}
\end{equation*}
$$

for all $\lambda \in R^{n}$. Since the mapping $\exp (-i \lambda \cdot): R^{n} \rightarrow S^{1}$ is continuous with respect to the compact convergence topology, homomorphism $\exp (-i \lambda \cdot): R^{n} \rightarrow S^{1}$ can be rewritten as factorized as follows $\exp (-i \lambda \cdot): \quad G=R^{n} \xrightarrow{\lambda \cdot} R \xrightarrow{\exp (-i \lambda \cdot)} S^{1}=U(1)$. The system $\{\exp (-i \lambda \cdot)\}$ constitutes an orthogonal basis in $H=L^{2}\left(R^{n}\right)$.

The main part of the paper is devoted to the generalization of the Fourier transform and the FourierStieltjes calculus, and developing the basic apparatus of a new approach to problems of quantum physics, so we propose a new type of the Wigner function and establish the Moyal identity for it. The Wigner function $W(\psi, \varphi)$ allows us to define the wavepacket transform $W_{\varphi}(\psi)$ with the window $\varphi$ by $W_{\varphi}(\psi)=$ $(2 \pi)^{\frac{n}{2}} W(\psi, \varphi)$ where the function $\psi \in S\left(R^{n}\right)$ is going backward and the window $\varphi \in S\left(R^{n}\right)$ moves forward at the same speed.

For a function $\psi \in L^{2}\left(R^{n} \oplus R^{n}\right) \cap L^{1}\left(R^{n} \oplus R^{n}\right)$, the classical symplectic Fourier transform $F_{\sigma}$ is given by $F_{\sigma}(\psi)(\lambda)=F \psi(J \lambda)$ where $J$ is the standard symplectic matrix $J=\left[\begin{array}{lll}0 & I \\ -I & 0\end{array}\right]$ and $I$ is an identity matrix. We propose to generalize the symplectic Fourier transform as a function defined on $\hat{G}_{\sigma}$ by an integral $F_{\sigma}(\psi)\left(\chi_{\sigma}\right)=\int \psi(h) \overline{\chi_{\sigma}(h)} d(\mu \otimes \mu)(h)$ where $\hat{G}_{\sigma}$ is a set of all continuous homomorphisms from $G \oplus G$ to $\operatorname{USp}(2)$, so $\hat{G}_{\sigma}$ constitutes a group with the operation of pointwise multiplication and the uniform convergence topology. For the generalized Wigner function, the analog of Moyal identity can be proved so for arbitrary $\varphi \in L^{2}(G)$ the mapping $\psi \mapsto W_{A}(\psi, \varphi)$ is a partial isometry on a closed subspace of $L^{2}(G \oplus G)$ thus the wavepacket transform can be defined by $W_{\varphi}^{A}(\psi)=A_{1} W_{A}(\psi, \varphi) \quad: \quad L^{2}(G) \rightarrow L^{2}(G \oplus G)$ with the window $\varphi \in L^{2}(G)$, this approach facilitates analysis of Bopp calculus.

## 2. The results of Peter-Weyl theorems

Let $G$ be a compact Hausdorff group equipped with a Haar measure $\mu$.
Definition 1. A complete Hilbert algebra of the square-integrable functions on the group $G$ is denoted by $L^{2}(G)$. According to the Peter-Weyl theorem, $L^{2}(G)$ algebra can be represented as an orthogonal sum $\oplus_{\alpha \in R} \Lambda_{\alpha}=$ $L^{2}(G)$ of topologically simple algebras $\Lambda_{\alpha}$, where $\Lambda_{\alpha}$ equals to matrix algebra $M_{n(\alpha)}(C)$ of $(n(\alpha))^{2}$-dimension, where $\alpha$ is a finite-dimensional representation of the compact group $G$. Each function $\Lambda_{\alpha}: G \rightarrow M_{n(\alpha)}(C)$ is a continuous function on the compact group $G$.

Definition 2. The set of all equivalence classes of an irreducible representation of the group $G$ is called $\hat{G}$.
From $\phi_{\alpha}=\sum_{k=1, . ., n(\alpha)} e_{k}$, we have $\sum_{k=1, . ., n(\alpha)} \psi * e_{k}=\psi * \phi_{\alpha}$ for the presentation $\psi=\sum_{\alpha} \psi * \phi_{\alpha}$. Each element $\Lambda_{\alpha}$ uniquely corresponds with a continuous function, so that for each finite-dimensional representation $\alpha$ there is a decomposition $\Lambda_{\alpha}=\oplus_{1 \leq k \leq n(\alpha)} \Lambda_{\alpha} * m_{k}$ where $m_{k}$ is an irreducible idempotent, and so that $\phi_{\alpha}=\sum_{k=1, \ldots, n(\alpha)} m_{k}$. Let $\left\{a_{k}\right\}_{1 \leq k \leq n(\alpha)}$ be a Hilbert basis in $\Lambda_{\alpha} * m_{1}$ with the condition $a_{k} \in m_{k} * \Lambda_{\alpha} * m_{1}$.

Definition 3. For every finite-dimensional representation $\alpha$, we define a matrix $M_{\alpha}(g)$ of $n(\alpha) \times n(\alpha)$-dimension with coefficients

$$
\begin{equation*}
a_{i j}(g)=(n(\alpha))^{-1}\left(a_{i}(g) * \overline{a_{j}\left(g^{-1}\right)}\right) \tag{5}
\end{equation*}
$$

for $1 \leq i \leq n(\alpha)$ and $1 \leq j \leq n(\alpha)$.
From definition 3 we have $a_{i i}=m_{i}$.
Definition 4. The Fourier transform $F(\psi)$ of the function $\psi \in L^{1}(G)$ is a mapping defined by

$$
\begin{equation*}
F(\psi)(\alpha)=\int \psi(h) M_{\alpha}\left(h^{-1}\right) d \mu(h) \tag{6}
\end{equation*}
$$

where $M_{\alpha}$ is a continuous unitary representation $M_{\alpha}: G \rightarrow U C\left(C^{n(\alpha)}\right)$ of the group $G$ in $C^{n(\alpha)}$.
We denote the set $\bigcap_{\alpha} M_{n(\alpha)}(C)$ by $\Theta(\hat{G})$.
Theorem (first theorem) 1. Let $G$ be a compact group then the mapping $F: L^{2}(G) \rightarrow L^{2}(\hat{G})$ defined by

$$
\begin{equation*}
F(\psi)(\alpha)=\int \psi(g) M_{\alpha}\left(g^{-1}\right) d \mu(g) \tag{7}
\end{equation*}
$$

is an isometric isomorphism.
For each element $\psi \in L^{2}(G)$, we have a representation

$$
\begin{equation*}
\psi=\sum_{\alpha} n(\alpha) \sum_{i, k=1, \ldots, n(\alpha)}\left\langle\left\langle F(\psi)(\alpha)\left(e_{i}(\alpha)\right),\left(e_{k}(\alpha)\right)\right\rangle\right\rangle \phi_{i k}(\alpha), \tag{8}
\end{equation*}
$$

where $\left\{e_{i}(\alpha)\right\}_{i=1, \ldots, n(\alpha)}$ is an orthonormal basis in $C^{n(\alpha)}$ and coordinate functions $\phi_{i k}$ are defined as

$$
\begin{equation*}
\phi_{i k}(\alpha)(g)=\left\langle M_{\alpha}(g) e_{i}(\alpha), e_{k}(\alpha)\right\rangle \tag{9}
\end{equation*}
$$

for all $g \in G$ and $i, k=1, \ldots, n(\alpha)$.
Theorem (second theorem) 2. Let G be a compact group then the inverse Fourier transform $F^{-1}: L^{2}(\hat{G}) \rightarrow L^{2}(G)$ is defined by

$$
\begin{equation*}
\psi(g)=\sum_{\alpha} n(\alpha) \operatorname{tr}\left(F(\psi)(\alpha) M_{\alpha}(g)\right) \tag{10}
\end{equation*}
$$

for any Fourier transform $F(\psi) \in L^{2}(\hat{G})$ of $\psi \in L^{2}(G)$ and the series converges in $L^{2}$.

## 3. The structure of $L^{2}$ - algebra

Let $G$ be a compact group then $L^{2}(G)$ is a separable complete Hilbert algebra. Let $\ell$ be a closed left ideal of $L^{2}(G)$ and let $\psi, \varphi \in \ell$ then there exist a sequence $\left\{e_{n}\right\}$ of irreducible self-adjoint idempotents $e_{n}$ of $\ell$ such that $\psi=\sum_{n} \psi e_{n}$ and $\langle\psi, \varphi\rangle=\left\langle\sum_{n} \psi e_{n}, \sum_{n} \varphi e_{n}\right\rangle$.

We remind matrix coefficients of $G$ are mappings $g \mapsto \phi^{*}\left(M_{\alpha}(g) \phi\right)$ for all $\phi^{*}, \phi \in C^{n(\alpha)}$.
Theorem (orthogonality of matrix coefficients). Let $\alpha$ be an irreducible representation of the compact group $G$ in the separable Hilbert space $H$. Then for all given $\psi_{1}, \varphi_{1}, \psi_{2}, \varphi_{2} \in H$, there is a strictly positive constant $d$ such that

$$
\begin{equation*}
\int_{G}\left\langle\alpha(g) \psi_{1}, \varphi_{1}\right\rangle \overline{\left\langle\alpha(g) \psi_{2}, \varphi_{2}\right\rangle} d \mu(g)=\frac{1}{d}\left\langle\psi_{1}, \psi_{2}\right\rangle\left\langle\varphi_{2}, \varphi_{1}\right\rangle \tag{11}
\end{equation*}
$$

The PeterWeyl theorem allows us to elucidate the structure of $L^{2}(G)$ algebra as follows.

Theorem. (First) 3. Let $G$ be a compact Hausdorff group then $L^{2}(G)$ is a complete Hausdorff-Hilbert algebra, which can be decomposed into a countable or finite Hilbert sum $L^{2}(G)=\oplus_{\alpha \in R} \Lambda_{\alpha}$ of topologically simple orthogonal algebras $\Lambda_{\alpha}$ under conditions $\Lambda_{\alpha_{1}} \Lambda_{\alpha_{2}}=\{0\}$ for all $\alpha_{1} \neq \alpha_{2}$. Each simple algebra $\Lambda_{\alpha}$ can be decomposed as a finite sum $\Lambda_{\alpha}=\oplus_{j} \ell_{j}$ of minimal left ideals such that there does not exist a pair of isomorphic ideals $\ell_{j}$. Since $G$ is a compact group, there exists an isomorphism of $\Lambda_{\alpha}$ to finite-dimensional matrix algebra $M_{n(\alpha)}$.
(Second) 4. Let $U: G \rightarrow U_{R}(H)$ be a unitary representation of a group $G$ in the separable Hilbert space $H$. Then Hilbert space H can be presented as a direct sum of finite irreducible representations each of the representations is equivalent to the matrix $\overline{M_{n(\alpha)}}$.

Proof. The first part follows from the density in Hilbert space $L^{2}(G)$ of the set of matrix coefficients of the compact group $G$ and the theorem of orthogonality of matrix coefficients. Under the density, we mean that for every fixed $\psi \in L^{2}(G)$ and for any $\varepsilon>0$ there exists a matrix coefficient $\tilde{\psi}$ such that $\|\psi-\tilde{\psi}\|<\varepsilon$.

To show the validity of the second part of the theorem, we employ the first part of the theorem so that for any $\varphi \in C(G)$ and $\varepsilon>0$ there exists matrix coefficient $\tilde{\psi}$ such that

$$
\begin{equation*}
\left\|\int_{G}(\varphi(g)-\tilde{\psi}(g)) \alpha(g) f d \mu(g)\right\|<\varepsilon\|f\| \tag{12}
\end{equation*}
$$

for all $f \in H$.
Let $\breve{\psi}(g)=\phi^{*}(\hat{\alpha}(g) \phi)$ be a matrix coefficient of the same dimensional dual representation $\hat{\alpha}$ on $n E$. We define a nonzero mapping $E^{*} \mapsto H$ by

$$
\begin{equation*}
\left(\phi \mapsto \int_{G} \phi^{*}\left(\hat{\alpha}\left(g^{-1}\right) \phi\right) \alpha(g) f d \mu(g)\right) \in \operatorname{Hom}^{G}\left(E^{*}, H\right) \tag{13}
\end{equation*}
$$

The image $\left(\phi \mapsto \int_{G} \phi^{*}\left(\hat{\alpha}\left(g^{-1}\right) \phi\right) \alpha(g) f d \mu(g)\right)\left(E^{*}\right)$ is a nonempty finite-dimensional subspace of $H$. We partially order a set $\Xi$ of finite-dimensional irreducible invariant subsets by the inclusion. Employing the choice axion, we have that there exists a maximal $\theta_{\max }$ element of the partially ordered set $\Xi$. Assuming the span of $\theta_{\max }$ does not coincide with Hilbert space $H$ then the complement of the span of $\theta_{\max }$ contains at least one irreducible subspace so $\theta_{\max }$ can not be maximal since their union is larger than $\theta_{\max }$, thus we obtain that the span of $\theta_{\max }$ does coincides with the Hilbert space $H$.

By the second part of the last theorem, we have obtained that let $U: G \rightarrow U_{R}\left(L^{2}(G)\right)$ a unitary representation of a compact group $G$ in $L^{2}(G)$. Then $L^{2}(G)$ decomposed into a direct sum of finite irreducible representations each of the representations is equivalent to the matrix $\overline{M_{n(\alpha)}}$.

## 4. Induce representation of a locally compact group

Let $G$ be a locally compact separable group and let $K$ be a closed subgroup of $G$. The $G / K$ is a metrizable space with a positive Borel measure $\mu$ on $G / K$. Our goal is to construct a unitary representation $\pi: G \rightarrow$ $U(H)$ and the Hilbert space $H$ under the assumption that the unitary representation $V: K \rightarrow U\left(H_{1}\right)$ is given and $H_{1}$ is a separable Hilbert space.

Let $\left\{\phi_{k}\right\}$ be a Hilbert basis of $H_{1}$ so that an arbitrary function $\psi: G / K \rightarrow H_{1}$ can be presented as a convergent sequence $\sum_{k} \psi_{k} \phi_{k}=\psi$, where $\psi_{k}: G / K \rightarrow C$ so that we take

$$
\begin{equation*}
\|\psi(g)\|_{H_{1}}^{2}=\sum_{k}\left|\psi_{k}(g)\right|^{2} \tag{14}
\end{equation*}
$$

The Egoroff theorem yields that the $\mu$-measurability of each function $\psi_{k}: G / K \rightarrow C$ of the sequence $\left\{\psi_{k}\right\}$ implies the $\mu$-measurability of the function $\psi: G / K \rightarrow H_{1}$. For the arbitrary basis $\left\{\phi_{k}\right\}$ of a Hilbert basis of $H_{1}$, we denote $L^{2}\left(G / K, H_{1}\right)$ the space of all $\mu$-measurable functions $G / K \rightarrow H_{1}$ so that we have the following equalities

$$
\int_{G / K}\|\psi(g)\|_{H_{1}}^{2} d \mu(g)=\sum_{k} \int_{G / K}\left|\psi_{k}(g)\right|^{2} d \mu(g)=\sum_{k}\left\|\psi_{k}\right\|_{L^{2}}^{2}
$$

The inner product in $L^{2}\left(G / K, H_{1}\right)$ is given by

$$
\int_{G / K}\langle\psi(g), \varphi(g)\rangle d \mu(g)=\sum_{k} \int_{G / K} \psi_{k}(g) \overline{\varphi_{k}(g)} d \mu(g)
$$

for any pair $\psi, \varphi \in L^{2}\left(G / K, H_{1}\right)$ which is presented as $\psi=\sum_{k} \psi_{k} \phi_{k}$ and $\varphi=\sum_{k} \varphi_{k} \phi_{k}$. Now, we can consider a quotient space of $L^{2}\left(G / K, H_{1}\right)$ as a space of all classes of equivalent functions of $L^{2}\left(G / K, H_{1}\right)$, this quotient space will be again denoted by $L^{2}\left(G / K, H_{1}\right)$.

Theorem. Let $G$ be a locally compact separable group and $K$ be a closed subgroup of $G$. Let $\mu$ be a positive Borel measure $\mu$ on $G / K$. Then the space $L^{2}\left(G / K, H_{1}\right)$ of all equivalence classes of all $\mu$-measurable functions $G / K \rightarrow H_{1}$ is a separable Hilbert space under the assumption that $H_{1}$ is a separable Hilbert space.

Proof. Assume the sequence $\left\{\psi_{j}=\sum_{k} \psi_{j, k} \phi_{k}\right\} \subset L^{2}\left(G / K, H_{1}\right)$ satisfies the Cauchy condition in $L^{2}\left(G / K, H_{1}\right)$, for any $\varepsilon>0$, there exists some $j_{0}$ such that the inequality

$$
\begin{aligned}
& \int_{G / K}\left\|\psi_{i}(g)-\psi_{j}(g)\right\|_{H_{1}}^{2} d \mu(g)= \\
& =\sum_{k} \int_{G / K}\left|\psi_{i, k}-\psi_{j, k}\right|^{2} d \mu(g) \leq \varepsilon
\end{aligned}
$$

holds for all $i, j>j_{0}$. Thus, the sequence $\left\{\psi_{i, k}\right\}_{i \geq 1} \subset L^{2}\left(H_{1}, C\right)$ satisfies the Cauchy condition. So, for any $\varepsilon>0$, there exists an element $\gamma_{k} \in L^{2}\left(H_{1}, C\right)$ and some $k_{0}$ such that we have

$$
\sum_{k=1, \ldots, k_{0}}\left\|\gamma_{k}-\psi_{j, k}\right\|_{L^{2}}^{2} \leq \varepsilon
$$

and

$$
\sum_{k=1, \ldots, k_{0}}\left\|\gamma_{k}\right\|_{L^{2}}^{2} \leq \sum_{k=1, \ldots, k_{0}}\left\|\gamma_{k}-\psi_{j, k}\right\|_{L^{2}}^{2}+\sum_{k=1, \ldots, k_{0}}\left\|\psi_{j, k}\right\|_{L^{2}}^{2} \leq \varepsilon+\left\|\psi_{j}\right\|_{L^{2}}^{2}
$$

so $\sum_{k=1, \ldots .}\left\|\gamma_{k}\right\|_{L^{2}}^{2}=\|\gamma\|^{2}<\infty$, the inequality

$$
\sum_{k=1, \ldots .}\left\|\gamma_{k}-\psi_{j, k}\right\|_{L^{2}}^{2} \leq \varepsilon
$$

holds for all $j>j_{0}$, thus, we have

$$
\lim _{j \rightarrow \infty} \psi_{j}=\gamma
$$

the limit is understood in a topology of $L^{2}\left(G / K, H_{1}\right)$. The set of functions $\psi=\sum_{k=1, \ldots, k_{0}} \psi_{k} \phi_{k}$ that can be presented as a finite linear combination of $\mu$-measurable $\psi_{k}(g)=\left\langle\psi(g), \phi_{k}\right\rangle$ and elements of the basis $\left\{\phi_{k}\right\}$ is dense in $L^{2}\left(G / K, H_{1}\right)$ with the natural norm.

Definition. Let a linear automorphism $\Lambda: G \times(G / K) \rightarrow G L\left(H_{1}\right)$ satisfies the conditions:
$\Lambda(e, a)=$ id $\left(H_{1}\right)$ for all $a \in G / K$
and

$$
\Lambda(g h, a)=\Lambda(g, h \cdot a) \cdot \Lambda(h, a)
$$

for all for all $g, h \in G$ and $a \in G / K$. Then the mapping $\Lambda: G \times(G / K) \rightarrow G L\left(H_{1}\right)$ will be called a cocycle of the group $G$ in a general linear group over $H_{1}$.

Theorem. Let $V: K \rightarrow U\left(H_{1}\right)$ be a unitary representation of $K$ in $H_{1}$. Let $\mu$ be an outer regular, $\sigma$-inner regular, finite on compact subsets Borel measure such that

$$
\begin{equation*}
\mu\left(g^{-1} E\right)=\mu(E) \tag{15}
\end{equation*}
$$

for all $g \in G$ and all $\mu$ - measurable sets $E$. Let each cocycle $\Lambda: G \times(G / K) \rightarrow U\left(H_{1}\right)$ satisfies the following conditions: for all $s \in K$, there is $\Lambda(s, a)=U(s)$; for each $t \in G$ and $\psi \in L^{2}\left(G / K, H_{1}\right)$, the mapping $G / K \rightarrow H_{1}$ given by $g \mapsto \Lambda(g, t)(\psi(g))$ is $\mu$ - measurable.

Then the homomorphism $\pi: G \rightarrow U\left(L^{2}\left(G / K, H_{1}\right)\right)$ induced by $\Lambda: G \times(G / K) \rightarrow U\left(H_{1}\right)$ according to

$$
(\pi(\psi))(g, h)=\left(\Lambda\left(h^{-1}, g\right)\right)^{-1}\left(\psi\left(h^{-1} g\right)\right), g \in G / K, \quad h \in G, \quad \psi \in L^{2}\left(G / K, H_{1}\right)
$$

is a unitary representation of the group $G$, if the mapping $h \mapsto(\pi(\psi))(g, h)$ is continuous as $G \rightarrow U\left(L^{2}\left(G / K, H_{1}\right)\right)$.
Proof. Assume $\psi \in L^{2}\left(G / K, H_{1}\right)$ and $g, h \in G$, we have

$$
\|(\pi(\psi))(g, h)\|_{H_{1}}=\left\|\left(\Lambda\left(h, h^{-1} g\right)\right)\left(\psi\left(h^{-1} g\right)\right)\right\|_{H_{1}}=\left\|\psi\left(h^{-1} g\right)\right\|_{H_{1}}
$$

so

$$
\int_{G / K}\left\|\psi\left(h^{-1} g\right)\right\|_{H_{1}}^{2} d \mu(g)=\int_{G / K}\|\psi(g)\|_{H_{1}}^{2} d \mu(g),
$$

thus, we obtain $\|(\pi(\psi))(h)\|_{L^{2}\left(G / K, H_{1}\right)}=\|\psi\|_{L^{2}\left(G / K, H_{1}\right)}$ for all $\psi \in L^{2}\left(G / K, H_{1}\right)$.
Thus, we have constructed the unitary representation $\pi: G \rightarrow U\left(L^{2}\left(G / K, H_{1}\right)\right)$ defined as $(\pi(\psi))(g, h)=$ $\left(\Lambda\left(h^{-1}, g\right)\right)^{-1}\left(\psi\left(h^{-1} g\right)\right)$ induced by the unitary representation $V: K \rightarrow U\left(H_{1}\right)$ and cocycle $\Lambda: G \times(G / K) \rightarrow$ $U\left(H_{1}\right)$.

## 5. The Gerald Folland modified method

Now, we are going to construct a Hilbert space $H$ and unitary representation $\tilde{\pi}: G \rightarrow H$ induced by $V: K \rightarrow U\left(H_{1}\right)$ assuming that $K$ is a closed subgroup of $G$ and $\mu$ is an outer regular, $\sigma$-inner regular, finite on compact subsets Borel measure such that $\mu\left(g^{-1} E\right)=\mu(E)$ for all $g \in G$ and all $\mu$-measurable sets $E$.

Let a continuous function $\phi: G \rightarrow H_{1}$ be supported on a compact set. We define a function $g \mapsto \varphi_{\phi}(g)$ by an integral formula

$$
\varphi_{\phi}(g)=\int_{K} V(h)(\phi(h g)) d v_{K}(h)
$$

where $v_{K}$ is Haar's measure on the subgroup $K$.
The Hilbert space $H$ is defined as the completion of the set of all functions $\varphi_{\phi}$ in the norm naturally induced by the inner product given by

$$
\left\langle\psi_{1}, \psi_{2}\right\rangle=\int_{G / K}\left\langle\psi_{1}(g), \psi_{2}(g)\right\rangle_{H_{1}} d \mu(g K)
$$

for all functions $\psi_{1}$ and $\psi_{2}$ such that sets $P\left(\sup p\left(\psi_{k}\right)\right), \quad k=1,2$ are compact and $\psi_{k}(g h)=V\left(h^{-1}\right)\left(\psi_{k}(g)\right)$, $k=1,2$ for all $g \in G, \quad h \in K$, where $P: G \rightarrow G / K$ is the quotient mapping.

The unitary representation $\tilde{\pi}: G \rightarrow H$ induced by unitary representation $V: K \rightarrow U\left(H_{1}\right)$ is defined as $\tilde{\pi}_{g}(\psi)(t)=\psi\left(g^{-1} t\right)$ for all $t \in G / K$.

Let $G$ be a compact separable group and let $K$ be a closed subgroup of $G$. Let us take $H_{1}=C$ then to construct a unitary representation $G \mapsto L^{2}(G / K, C)$, we can use the Peter-Weyl theorem to consider a restriction $W: K \rightarrow U\left(C^{n(\alpha)}\right)$ of representation $M_{\alpha}: G \rightarrow U\left(C^{n(\alpha)}\right)$ on the subgroup $K$. By the second Peter-Weyl theorem, we can define orthogonal projection $P_{n(\alpha)}: C^{n(\alpha)} \rightarrow P_{n(\alpha)}\left(C^{n(\alpha)}\right) \subset C^{n(\alpha)}$ by

$$
M_{\alpha}\left(\frac{1}{n(\bar{\alpha})} \chi(\bar{\alpha})\right)=\frac{1}{n(\alpha)} \int_{K} M_{\alpha}(h) \overline{\chi(\alpha)(h)} d v_{K}(h)
$$

So, there is decomposition $C^{n(\alpha)}=\underset{\beta}{\oplus} P_{\beta}\left(C^{\beta}\right)$ where $\beta$ is representation on $K$, and the Hilbert space $L^{2}(G / K, C)$ can be presented in the form $\oplus L_{\alpha}$ of a Hilbert series of subspaces $L_{\alpha} \subset \Lambda_{\alpha}$ so that $L_{\alpha}=$ $\underset{i=1, \ldots, d, d=1, \ldots, n(\alpha)}{\oplus} C \cdot\left(n(\alpha) a_{i}(g) * \overline{a_{j}\left(g^{-1}\right)}\right)$ if the trivial representation $\gamma$ of the subgroup $K$ is $d=\frac{\alpha}{\gamma} \geq 1$ times in the restriction of $M_{\alpha}$ to $K$.
6. The symplectic Fourier transform and a generalization of the ambiguity function and Wigner functions

The set $S p(2 n, K)$ of all symplectic matrices over the field $K$ is called a symplectic group. The compact symplectic group $S p(2 n, C) \bigcap U(2 n)$ is denoted by $U S p(2 n)$.

Now, let $G$ be a compact communicative group with a Haar measure $\mu$ on $G$. We define a group $\hat{G}_{\sigma}$ as a group of all continuous homomorphisms from $G \oplus G$ to USp (2).

Definition 5. The symplectic Fourier transform $F_{\sigma}$ of $\psi \in L^{2}(G \oplus G) \cap L^{1}(G \oplus G)$ is defined by

$$
\begin{equation*}
F_{\sigma}(\psi)\left(\chi_{\sigma}\right)=\int_{G \times G} \psi(h) \overline{\chi_{\sigma}(h)} d(\mu \otimes \mu)(h) \tag{16}
\end{equation*}
$$

for all $\chi_{\sigma} \in \hat{G}_{\sigma}$.
The inverse of the symplectic Fourier transform $F_{\sigma}^{-1}$ is the same Fourier transform $F_{\sigma}$.
Now, let $A$ be a compact communicative algebra.
Let $\psi, \varphi \in L^{2}(A)$. We define the pair of functions $\operatorname{Am}(\psi, \varphi)$ and $W_{A}(\psi, \varphi)$ by formulae

$$
\begin{equation*}
\operatorname{Am}(\psi, \varphi)(\chi, z)=\int_{A} \overline{\chi(y)} \psi\left(y+\frac{1}{2} z\right) \overline{\varphi\left(y-\frac{1}{2} z\right)} d \mu(y) \tag{17}
\end{equation*}
$$

and

$$
\begin{equation*}
W_{A}(\psi, \varphi)(\chi, z)=\int_{A} \overline{\chi(y)} \psi\left(z+\frac{1}{2} y\right) \overline{\varphi\left(z-\frac{1}{2} y\right)} d \mu(y) \tag{18}
\end{equation*}
$$

these functions will be called ambiguity and Wigner functions respectively.
The classical ambiguity and Wigner functions are defined by integrals with respect to the Lebesgue measure

$$
\begin{equation*}
\operatorname{Amb}(\psi, \varphi)(p, z)=\left(\frac{1}{2 \pi}\right)^{n} \int_{A} \exp (-i p \cdot y) \psi\left(y+\frac{1}{2} z\right) \overline{\varphi\left(y-\frac{1}{2} z\right)} d y \tag{19}
\end{equation*}
$$

and

$$
\begin{equation*}
W(\psi, \varphi)(p, z)=\left(\frac{1}{2 \pi}\right)^{n} \int_{A} \exp (-i p \cdot y) \psi\left(z+\frac{1}{2} y\right) \overline{\varphi\left(z-\frac{1}{2} y\right)} d y \tag{20}
\end{equation*}
$$

By changing variables $u=y+\frac{1}{2}, \quad v=y-\frac{1}{2} z$, we obtain that the classical Wigner function has an exact marginal $\langle W(\psi, \varphi)(\cdot, z)\rangle=\psi(z) \overline{\varphi(z)}$ and $\langle W(\psi, \varphi)(p, \cdot)\rangle=F(\psi(p)) \overline{F(\varphi(p))}$. So, we introduce the next definition.

Definition 6. . Let $\psi, \varphi$ be $L^{2}(A)$. If functions $A m(\psi, \varphi)$ and $W_{A}(\psi, \varphi)$ defined (17) and (18) such that $W_{A}(\psi, \varphi)$ satisfies the marginal conditions

$$
\int_{A} W_{A}(\psi, \varphi)(\chi, z) d \mu(\chi)=\psi(z) \overline{\varphi(z)}
$$

and

$$
\int_{A} W_{A}(\psi, \varphi)(\chi, y) d \mu(y)=F(\psi(\chi)) \overline{F(\varphi(\chi))}
$$

then functions $A m(\psi, \varphi)$ and $W_{A}(\psi, \varphi)$ are called the ambiguity and Wigner functions respectively. The centralizer $C_{A}(a)$ of $a$ in $A$ is the set given by

$$
C_{A}(a)=\{g \in A: g a=a g\}
$$

For $g, h \in A$ we have

$$
\chi(g) \overline{\chi(h)}=\left\{\begin{array}{l}
\left|C_{A}(g)\right|, \quad \text { if } g \text { and } h \text { are conjugate } \\
0 \text { otherwise. }
\end{array}\right.
$$

We calculate an integral

$$
\left.\left.\begin{array}{l}
\int_{\hat{A}} \int_{A} W_{A}\left(\psi_{1}, \varphi_{1}\right)(\chi, z) W_{A}\left(\psi_{2}, \varphi_{2}\right)(\chi, z) d \mu(z) d \mu(\chi)= \\
=\int_{\hat{A}} \int_{A} \int_{A} \int_{A} \overline{\chi(y)} \chi(x) \psi_{1}\left(z+\frac{1}{2} y\right) \overline{\psi_{2}\left(z+\frac{1}{2} x\right) \times} \\
\varphi_{1}\left(z-\frac{1}{2} y\right)
\end{array} \varphi_{2}\left(z-\frac{1}{2} x\right) d \mu(y) d \mu(x) d \mu(z) d \mu(\chi)=-\overline{\psi_{2}}\right\rangle\left\langle\overline{\varphi_{1}}, \varphi_{2}\right\rangle\right)
$$

so we have obtained an analog of the Moyal identity in the form of the following theorem.

## Theorem 5. The Moyal equality

$$
\left\langle W_{A}\left(\psi_{1}, \varphi_{1}\right), W_{A}\left(\psi_{2}, \varphi_{2}\right)\right\rangle_{L^{2}}=|A|\left\langle\psi_{1}, \overline{\psi_{2}}\right\rangle_{L^{2}}\left\langle\overline{\varphi_{1}}, \varphi_{2}\right\rangle_{L^{2}}
$$

or

$$
\left\langle W_{A}\left(\psi_{1}, \varphi_{1}\right), W_{A}\left(\psi_{2}, \varphi_{2}\right)\right\rangle_{L^{2}}=|A|\left(\psi_{1}, \psi_{2}\right)_{L^{2}} \overline{\left\langle\varphi_{1}, \varphi_{2}\right\rangle_{L^{2}}}
$$

holds for all $\psi_{1}, \varphi_{1}, \psi_{2}, \varphi_{2} \in L^{2}(A)$.
